Field of the Invention The present invention relates generally to a polythiophene based switching element, and more particularly to a polythiophene/silicon based thin film switching element. 2. Description of the Related Art The use of ferroelectric materials as materials for the switching elements of integrated switching circuits is well known. The ferroelectric materials generally have a characteristic of a spontaneous polarization that may be changed or switched in response to an applied electric field and electric charge. Several patents have issued relating to ferroelectric switching elements, such as U.S. Pat. No. 4,734,856 to Dietz et al. and U.S. Pat. No. 4,859,680 to Adams et al. The ferroelectric element may also include a non-conducting material, such as SiO2 or insulating polymers, disposed between the top and bottom electrodes of the ferroelectric element. By disposing the non-conducting material, the ferroelectric element can be switched with a voltage smaller than that which would be required to switch the entire ferroelectric element, thus reducing power consumption and the risk of damage to the ferroelectric element. In prior art ferroelectric switching elements, the switching is known to occur only through the movement of the polar electrons from the bottom electrode of the switching element to the top electrode. By controlling the movement of the polar electrons, the switching element can be controlled. Electro-optical devices are essentially two-terminal circuits in which a light beam is directed from a first terminal of a circuit to a second terminal. By controlling the light beam, various patterns can be displayed. An example of a modern electro-optical device is a liquid crystal display, in which an electric field applied to a thin layer of liquid crystal molecules re-arranges the molecules to create a parallel alignment of molecules, which may affect the amount of light transmitted by the liquid crystal material. The amount of light that is allowed to pass from a material or a thin film can be controlled. In addition, by controlling the electric field across the electrodes of the liquid crystal, various patterns can be displayed. For example,

Field of the Invention The invention concerns an amplifier circuit, and, more particularly, it relates to a current-cascode amplifier which is suitable as an input stage of a differential amplifier. 2. Prior Art In order to provide a quick, wide-band, low-distortion amplifier, it is necessary to use a cascode amplifier of the differential input type. This is an amplifier circuit that provides a signal which is the average of two input voltages, either positive or negative. FIG. 1 is a circuit diagram of a prior-art cascode amplifier. In FIG. 1, transistors M5 and M6 are the input transistors of the amplifier. Transistors M1, M2, M3, M4, M7 and M8 serve as emitter followers. As shown in FIG. 1, the input terminals are connected in parallel with resistors R1 and R2 in series, and a constant current source I1 for supplying currents to input terminals is provided. FIG. 2A shows an equivalent circuit of the amplifier of FIG. 1, and FIG. 2B shows a circuit diagram of the amplifier. In FIG. 2A, resistors R1 and R2 in series supply a current corresponding to the input voltage to input transistors M5 and M6. While the input transistors M5 and M6 are turned on, the constant current source I1 supplies a current corresponding to the input voltage. Therefore, the input transistors M5
